access market is biased downwards." *Further Notice*, App. B at 26. This conclusion is confirmed by the results of the Commission's imputed X study (*Further Notice*, App. C), in which X-factors based on interstate data range from 6.61% to 7.71% -- significantly higher than the total company X-factors obtained from the TFP study.

Despite these findings, the staff has continued to use total company data in its recent TFP study "because of the difficulty of separating interstate and intrastate costs for the TFP calculations" (*Further Notice* at 37). Indeed, the Commission has long maintained that the difficulty in calculating an X-factor based on interstate-only TFP growth is quantifying the amount of inputs used to provide interstate services. As shown below, the "direct" method of calculating the X-factor eliminates this problem. Under the direct method, the X-factor is calculated on the basis of output and revenue growth, without separately calculating the TFP and input price components of the X-factor.[2]

This approach has many advantages. It makes calculating an interstate-only X-factor a simple matter, because measurement of LEC interstate outputs and LEC interstate revenues is easy. It properly focuses attention on those variables that actually determine the historical X-factor and eliminates the complex calculations needed to develop indices that have no real bearing on the results. Moreover, limiting the analysis to interstate services produces an X-Factor that is more appropriate for regulating these interstate services. It also has the virtue of avoiding the complications inherent in measuring output of other, non-interstate LEC services. Most of the LECs' interstate output consists of wholesale access services provided to other carriers, which are more conducive to measurement in terms of relatively simple physical units.

Derivation of the Direct Method

We can derive a formula for calculating X-factors directly by examining the components of the Commission's X-factor model. In the Commission's TFP studies, the historically justified X-factor is calculated according to the following formula (*Further Notice*, App. B at 44):

(1) $X = (\%\Delta TFP_{LEC} - \%\Delta TFP_{US}) + (\%\Delta IP_{US} - \%\Delta IP_{LEC})$,

where the X-factor is expressed in terms of two components: the historical growth in LEC productivity ($\%\Delta TFP_{LEC}$) relative to that of the entire U.S. economy ($\%\Delta TFP_{US}$), and the historical trend in LEC input prices ($\%\Delta IP_{LEC}$) relative to input prices for the entire economy ($\%\Delta IP_{US}$). Growth in TFP is defined as growth in an index of total outputs (Q) minus growth in an index of total inputs (N), so that equation (1) can be written as:

(2) $X = (\%\Delta Q_{LEC} - \%\Delta N_{LEC} - \%\Delta TFP_{US}) + (\%\Delta IP_{US} - \%\Delta IP_{LEC})$

---

[2] This analysis was first presented in the paper "The Use of Productivity Studies in Price Cap Regulation: What do the FCC's X-factor Calculations Really Measure?" Stephen Friedlander, 18th Annual Conference of the Center for Research in Regulated Industries, Rutgers University, May 27.1999.

$$X = \%\Delta Q_{LEC} - (\%\Delta N_{LEC} + \%\Delta IP_{LEC}) - \%\Delta TFP_{US} + \%\Delta IP_{US.}$$

The term in parentheses ($\%\Delta N_{LEC} + \%\Delta IP_{LEC}$) represents growth in LEC input costs or growth in factor payments. In the Commission's 1997 TFP study, this term is exactly equal to growth in total revenues. In the 1999 TFP study, it is approximately equal to growth in revenues adjusted for excess LEC earnings and excess employee benefits. This can be shown by examining how the input price and quantity indexes are developed.

The input quantity index (N) consists of a chained Fisher Ideal Index comprised of three factors: <u>labor</u> measured in terms of number of employees; <u>materials</u> measured in terms of materials expense deflated by a materials price index; and a <u>capital stock</u> based on the Perpetual Inventory Model. The growth in this index can be expressed as:

(3) $\%\Delta N_{LEC} = W1*(\%\Delta NEM) + W2*(\%\Delta(MAT/MATP)) + W3*(\%\Delta K),$

where:
   N_{LEC} = index of total LEC inputs
   NEM = number of employees
   MAT = materials expense
   MATP = materials price index
   K = capital stock
   W1, W2, W3 = payments to each factor as a fraction of total factor payments.

The input price index is also a chained Fisher Ideal Index, with the price of labor measured in terms of average compensation per employee, the price of materials measured by the materials price index, and the price of a unit of capital measured as "property income" divided by the capital stock. Growth in the input price index is given by:

(4) $\%\Delta IP_{LEC} = W1*[\%\Delta(TCOMP/NEM)] + W2*[\%\Delta MATP] + W3*[\%\Delta(PINC/K)],$

where:
   TCOMP = total compensation
   PINC = property income
   K = capital stock.

Note that several items that appear in the denominators of the terms in one index appear in the numerators of the other index. When equations (3) and (4) are added together, these terms effectively "cancel out":

$\%\Delta N_{LEC} + \%\Delta IP_{LEC} = W1*(\%\Delta NEM + \%\Delta TCOMP - \%\Delta NEM)$
$+ W2*(\%\Delta MAT - \%\Delta MATP + \%\Delta MATP) + W3*(\%\Delta K + \%\Delta PINC - \%\Delta K).^{3}$

---

[3] With growth rates expressed in terms of logarithmic first differences, the growth rate of a ratio (A/B) is equal to growth in the numerator (A) minus growth in the denominator (B).

(5) $\%\Delta N_{LEC} + \%\Delta IP_{LEC} = W1*(\%\Delta TCOMP) + W2*(\%\Delta MAT) + W3*(\%\Delta PINC)$.

The growth in LEC inputs plus growth in input prices can thus be expressed as a weighted average of the growth rates of the payments to each factor. Similarly, the growth in total factor payments (TCOMP+MAT+PINC) can be expressed as a weighted average of the growth rates for each of its components, using the same revenue weights as above:

$\%\Delta(TCOMP+MAT+PINC) = W1*(\%\Delta TCOMP) + W2*(\%\Delta MAT) + W3*(\%\Delta PINC)$.

The growth in LEC inputs plus growth in input prices is thus equal to the growth in total factor payments.

In the 1997 TFP study, total factor payments equal total revenues because of the way property income is defined -- as total revenue *minus* compensation *minus* materials expense. In the 1999 TFP study, excess earnings are removed from property income, while excess benefits are removed from employee compensation. Total factor payments are thus equal to total revenues minus these adjustments, and the following equality holds:

(6) $\%\Delta REV_{LEC} = \%\Delta N_{LEC} + \%\Delta IP_{LEC}$,

where REV refers to LEC revenue and reflects whatever adjustments are made in the analysis. Substituting (6) into (2) shows that the X-factor can be calculated as:

(7) $X = \%\Delta Q_{LEC} - \%\Delta REV_{LEC} - \%\Delta TFP_{US} + \%\Delta IP_{US}$.

The 1999 TFP study differs slightly from the 1997 study in its measurement of the capital quantity index. The capital quantity index in the 1997 study is based on the computed capital stock as of the end of the prior year. Since the capital price index - based on property income divided by the capital stock - is also calculated with respect to the prior year's capital stock, the capital stock numbers cancel out when the capital price and quantity indexes are combined. In the 1999 study, on the other hand, the capital quantity index is based on the computed capital stock for the current year, while the capital price index is calculated with respect to the prior year's capital stock. (It is not clear from Appendix B in the *Further Notice* whether this difference is intentional.) When the two indexes are combined, the capital stock numbers do not cancel out. That is,

(5') $\%\Delta N_{LEC} + \%\Delta IP_{LEC} = W1*(\%\Delta TCOMP) + W2*(\%\Delta MAT)$
$+ W3*[\%\Delta PINC + \%\Delta K(t) - \%\Delta K(t-1)]$,

and the X-factor is calculated as:

(8) $X = \%\Delta Q_{LEC} - \%\Delta REV_{LEC} - W3*[\%\Delta K(t) - \%\Delta K(t-1)] - \%\Delta TFP_{US} + \%\Delta IP_{US}$

4

As a result, direct calculation of the X-factor based on equation (7), yields numbers that differ slightly from the Commission's calculation, which is equivalent to equation (8). The differences can be fairly significant for individual years, but tend to average out over longer periods. For the 1991-98 period, for instance, the two calculations yield very similar results for total company X-factors: 6.336% using the direct calculation versus 6.334% with the FCC's calculation.

The implications of this analysis are clear. X-factors applicable to the LECs' interstate access services can be calculated directly on the basis of interstate output and interstate revenue using equation (7). There is no need to measure explicitly interstate inputs or interstate productivity. The principal difficulty in calculating an interstate-only X-factor dissolves away.

Indeed, the Commission staff has all but acknowledged these facts, by finding that "most measurement errors associated with the prices of the inputs will tend to cancel out so that the impact on the productivity offset will, in general, be minimal" (*Further Notice*, App. B at 27) and that "increasing (decreasing) the price of one of the factor inputs will lower (raise) TFP$_{LEC}$ but it will reduce (raise) the input price differential resulting in little net change in X" (*Further Notice*, App. B at 31).[4] Equation (5) shows that input prices and input quantities both "cancel out" when calculating the X-factor. The X-factor can thus be calculated directly without developing input price and quantity indexes.

Measurement of Inflation in the Commission's Study

AT&T also sets forth here an alternative method for accounting for inflation in the Commission's TFP methodology. A major objective in the TFP study is to determine "the expected amount that national output prices grow faster than industry input prices" (p. 42). In the Commission's X-factor equation (equation (26) or (27) in Appendix B), the change in output prices in the economy as a whole is represented by the change in U.S. input prices (%ΔIP$_{US}$) minus the change in U.S. productivity (%ΔTFP$_{US}$). That is, changes in economy-wide input prices and productivity act as a surrogate for economy-wide inflation in the X-factor equation.

There is no reason, however, why economy-wide inflation cannot be measured directly by using the GDP price index in place of the terms (-%ΔTFP$_{US}$ + %ΔIP$_{US}$) in equations (26) and (27).[5] Although output prices in the economy tend to be a function of input prices and productivity (at least in theory), it turns out that historical growth in the GDP price index has been somewhat greater than growth in U.S. input prices minus growth in U.S. productivity, particularly in recent years since 1995. Since the price cap rules utilize changes in the GDP price index (GDP-PI) to adjust rate levels, it is more

---

[4] The Commission staff apparently intended to say "raise (lower) TFP" rather than "lower (raise) TFP."
[5] Data on U.S. input prices and productivity may be useful for comparing the trends in LEC input prices and productivity to economy-wide trends, but these data are not needed for the purpose of calculating the X-factor.

appropriate to compare the trend in LEC input costs to the trend in GDP-PI. Equation (7) then becomes:

(9) $X = \%\Delta Q_{LEC} - \%\Delta REV_{LEC} + \%\Delta GDP\text{-}PI,$

which can also be written as:

(9') $X = \%\Delta GDP\text{-}PI - \%\Delta(REV_{LEC}/Q_{LEC}).$

With excess earnings removed from LEC revenues, REV_{LEC} represents total LEC costs (i.e., factor payments) and the term (REV_{LEC}/Q_{LEC}) represents costs per unit of output. The X-factor is thus equal to the difference between the inflation rate and the trend in unit costs. Use of equation (9) to calculate the historically justified X-factor is fully consistent with the criteria established by the Commission in this proceeding:

> "First, the X–Factor should be economically meaningful. That is, it should provide a reliable measure of the extent to which changes in the LECs' unit costs have been less than the level of inflation. Second, the X-Factor should ensure that ongoing gains by the LECs in reducing unit costs are passed through to consumers. Third, calculation of the productivity offset should be reasonably simple and based on accessible and verifiable data."[6]

By measuring the extent to which changes in the LECs' unit costs have been less than the level of inflation, use of equation (9) or (9') clearly promotes the Commission's objective of ensuring "that ongoing gains by the LECs in reducing unit costs are passed through to consumers." It also satisfies the criterion of using "accessible and verifiable data," since use of the GDP price index as a benchmark avoids the need to forecast the last year of U.S. productivity growth, for which 1998 data is not yet available.

Cost of Capital Adjustment

In order to use equations (7) or (9) to calculate interstate X-factors, the revenue data needs to be adjusted to remove earnings in excess of the LECs' cost of capital. The accompanying charts set forth AT&T's calculations based on the Commission staff's proposed cost of capital adjustment, as well as separate calculations based on AT&T's alternative cost of capital adjustment.

The first approach uses the Commission's adjustments for excess earnings and excess employee benefits. As shown on the right-hand side of Table A-1, "Adjusted total factor payments," as calculated by the Commission in Table B-10, are divided by total revenue in Table A-1. (Table A-1 is a modified version of staff's Table B-2.) The resulting ratio is then applied to interstate service revenue to obtain interstate revenue adjusted for excess earnings and employee benefits. These calculations have the effect of

---

[6] FCC, *Fourth Further Notice of Proposed Rulemaking in CC Docket No. 94-1*, Sept. 27, 1995, Paragraph 16.

6

reducing interstate revenue by the same percentage as total revenue is reduced by the Commission's adjustments.

In order to confirm the reasonableness of these calculations, AT&T constructed an alternative methodology. The second approach removes excess earnings from interstate revenues for 1991 through 1998, based on AT&T's estimate of the LECs' cost of capital.

For 1998, an 8.63% rate of return on average net investment is used to represent the LECs' cost of capital. This figure represents the mid-point estimate of the RBOCs' weighted average cost of capital as of December 1997, as reported in AT&T's recent submission in Docket 98-166.[7] The 8.63% figure is very close to the competitive rates of return for 1998 used by the Commission in its imputed X study (*Further Notice*, Appendix C), which consist of 8.68% for all LECs and 8.66% for the RBOCs.

The 11.25% rate of return prescribed by the Commission in 1990 is used as the cost of capital in 1990 and 1991. Competitive rates of return for the years between 1991 and 1998 are based on a straight-line interpolation of 11.25% in 1991 and 8.63% in 1998. The resulting downward trend from 1991 to 1998 is similar to the trend in corporate bond rates used by the Commission to develop its cost of capital index. For the years prior to 1990, it is assumed that interstate earnings were commensurate with the cost of capital, and no adjustment is made to interstate revenue. Although this assumption is made purely for the sake of simplicity, the assumption is reasonable because interstate access services were under rate of return regulation prior to 1991.

Adjustments to interstate revenue for the years 1991 to 1998 are shown on the right-hand side of Table A-2. Revenues are reduced by an *earnings adjustment* that represents the change in earnings needed to provide the *competitive ROR* and a *tax adjustment* equal to 39% of the earnings adjustment.[8] No adjustment is made for excess employee benefits.[9]

Correction Of A Minor Error In The Staff's Calculations

Finally, the Commission's spreadsheets contained a minor error, whereby the growth rates in LEC input prices for 1986 through 1989 were incorrectly copied from Table B-13 to Table B-12. As shown in the corrected version of Table B-12 included here (Table A-3), this reduces the average 1986-1998 X-factor from 6.02% to 5.95%, but has no effect on the average 1991-98 X-factor.

---

[7] Responsive Submission of AT&T Corp. to Prescription Proceeding Direct Case Submissions and Reply Comments on the Notice of Proposed Rulemaking (CC Docket No. 98-166), March 16, 1999. Attachment 10.

[8] The Commission used a 39% marginal tax rate in its imputed X study.

[9] An adjustment similar to that of the Commission could easily be made, but the adjustment has little effect on the X-factor for multi-year periods.

Results

X-factors for each year from 1986 through 1998 were calculated based on the modifications to the Commission's Option 2 methodology described above. These are presented in Table A-4, which uses the staff's capital cost index. Rolling averages, similar to those that the Commission relied on in the *1997 Price Cap Order*, were then calculated for the periods ending in 1995 and 1998.

Estimates utilizing the Commission's adjustments for excess earnings and excess employee benefits are presented in Table A-6. The first column shows Interstate X-factors based on equation (7) above, for which the median value is 10.1% for the 1986-1995 period and 9.5% for the 1986-1998 period. X-factors obtained using equation (9), in which growth rates for U.S. input prices and total factor productivity are replaced with growth in the GDP-PI, are shown in the second column, with median values of 10.1% for the 1986-1995 period and 9.9% for the 1986-1998 period. Because growth in the GDP price index has been somewhat greater than growth in U.S. input prices minus growth in U.S. productivity in the years since 1995, the use of GDP-PI causes the X-factors to be about 0.3 percentage points higher for the periods ending in 1998. For periods ending in 1995, there is little difference between the two measures of inflation.

Annual X-factor calculations based on AT&T capital cost index are presented in Table A-6, and rolling averages based on this approach are shown in Table A-7. Estimated X-factors are generally in the same range as those shown in Table A-5. The calculation of X-factors for individual years, from which the averages in Tables A-5 and A-7 are obtained, is shown in Tables A-4 and A-6 respectively. Column H shows interstate X-factors based on equation (7), while X-factors obtained using equation (9) are shown in Column J. Also shown in Tables A-4 and A-6 are total company X-factors based on direct calculation.

Comparison With Results Under the Staff's Option 2 Study

X-factors calculated in this manner, moreover, are very similar to those obtained under the Commission's Option 2 methodology, using interstate outputs rather than total-company outputs. This is essentially the approach previously used by AT&T in its "Performance-Based Model" to estimate interstate X-factors, based on the assumption that inputs grow at the same rates for interstate access as for the LECs' other regulated telephone services.[10] Calculations are shown on Table A-8, which is basically the same as the Commission's Table B-12, except that growth rates for interstate output rather than total company output are used in Column B. The average X-factors are strikingly similar to those reported on Table A-5, with median values of 10.0% for the 1986-95 period and 9.5% for the 1986-98 period. Table A-9 reports average TFP growth rates for specified periods, based on the results from Table A-8.

Table A-1. LEC Revenue ($) by Type of Service[1] - 1985-1998

Year	Local Service Revenue	Intrastate Toll and Intrastate Access Service Revenue	Interstate Service Revenue (A)	Total Revenue (B)
1985	$26,960,554,164	$13,047,095,682	$14,366,305,727	$54,373,955,573

1991-95	8.09	7.89	10.54
1996-98	9.75	8.93	8.39

Appendix B
TECHNICAL CORRECTION TO THE STAFF IMPUTED X STUDY (OPTION 3)
Stephen Friedlander, AT&T

The Staff's imputed X study (Option 3) attempts to simulate the impact of alternative X-factors on interstate revenues and earnings with the purpose of determining the X-factors that result in local exchange carriers ("LECs") earning a "competitive" interstate rate of return in either 1995 or 1998. The purpose of this appendix is to identify and correct a minor flaw in the imputed X study that causes the imputed X-factor for the 1991 to 1998 period to be slightly understated.

The calculations in Table C-1 of the study improperly fail to account for the price cap "reinitialization" that occurred in July 1997. As a result of this reinitialization, price cap indexes as of July 1997 and thereafter were calculated based on an X-factor of 6.5%. Thus, the imputed X study's X-factor for 1996 (shown in the column labeled "Actual X-factor" in Table C-1) should be 6.5% rather than 5.3%.

The study's failure to account for the 1997 reinitialization has the effect of overstating the differential between revenues under existing X-factors and the revenues that would result under higher X-factors. As a result, the earnings associated with higher X-factors are understated, and the X-factors needed to produce a given level of earnings are understated.

This minor flaw is corrected in Table B-1 (attached hereto), which replicates the Commission's Table C-1 in Appendix C of the *Further Notice*, except that the "Actual X-Factor" for 1996 has been changed from 5.3% to 6.5%.

Once this correction is made, the X-factor that causes the LECs to earn a "competitive" interstate rate of return (*i.e.*, 8.68%) in 1998 increases from 7.71% to 7.87%. The impact of a 7.87% X-factor on LEC revenues, LEC rates of return, and consumer benefits is shown in Table B-2 (attached hereto).

Appendix C
CALCULATION OF A NEW CONSUMER PRODUCTIVITY DIVIDEND
Stephen Friedlander, AT&T

The D.C. Circuit remanded the FCC's 1997 decision retaining the Consumer Productivity Dividend ("CPD") on the ground that the Commission had failed to explain its "choice of the amount -- 0.5%." 188 F.3d at 527. As the Court observed, the LEC petitioners did not dispute the FCC's rationale that retention of the CPD in some amount was appropriate because the FCC's newly adopted rule eliminating all sharing requirements would increase the price cap LECs' productivity in the future. Id. Because there is no dispute about the Commission's *reason* for retaining the CPD, the only question on remand is the level at which the CPD should be set to reflect the likely impact of the elimination of sharing on the LECs' productivity.

To put the matter in mathematical terms, our task is to find a reasonable estimate of the difference, all else being equal, between the LECs' potential productivity gains in a sharing regime (which we will denote X_S) and the LECs' potential productivity gains in a no-sharing regime (X_{NS}). The CPD would then be calculated as the estimated difference between these two quantities, *i.e.*, X_{NS} - X_S, and this quantity would then be added to the historical component of the X-factor. This is consistent with the Commission's rationale in adopting the original CPD, namely, that it "assure[s] that the first benefits of price caps flow to customers in the form of reduced rates." 5 FCC Rcd. at 6799.

There are a number of possible approaches to calculating this difference. All of them point in the same direction -- toward a CPD of at least 1.5 percent.

1. One approach is suggested by the FNPRM's references to two studies in the record -- one performed by Strategic Policy Research ("SPR") on behalf of Southwestern Bell and the other sponsored by the Ad Hoc Telecommunications Users Committee ("Ad Hoc").[1] These studies show that the imposition of sharing suppresses the LECs' incentives for productivity growth and, conversely, that the complete elimination of sharing would substantially increase the LECs' productivity.

Neither study attempts to measure directly the impact on productivity of the elimination of sharing. But a rough estimate of that impact can be derived from the SPR study, when combined with other data regarding the impact on productivity of the Commission's move from rate-of-return regulation to a price cap system with sharing.

a.   Both studies derive a measure of the efficiency incentives faced by a LEC under different regulatory regimes. If we denote this incentive as I, then I_C is the efficiency incentive faced in a fully competitive market, and is equal to unity.

SPR calculates that the efficiency incentive in a no-sharing regime is only about 35% of that prevailing in a competitive market; thus I_{NS} is 0.35. SPR further calculates that the incentive

---

[1] *See* Comments of Southwestern Bell Telephone Company, CC Docket No. 94-1, App. SPR (May 9, 1994) ("SPR study"); Reply Comments of Ad Hoc, CC Docket No. 94-1, 14-18 (June 30, 1994).

in a sharing scenario (I_S), where firms are required to share 50% of their additional earnings above a certain threshold, is 0.18. Thus, the efficiency incentive in a no-sharing regime is about twice what it is in a sharing regime. Moreover, the efficiency incentive in a rate-of-return regime (with a one-year lag) (I_{ROR}) is only slightly smaller, at 0.14, than the efficiency incentive in a sharing regime.

In this model, then, the adoption of a price cap system with sharing would be expected to increase a LEC's incentives for efficiency by about 29 percent (.4/.14) as compared with a ROR regime. And the move from a price cap system with sharing to one without sharing would increase a LEC's efficiency incentives by about 94 percent ((.35-.18)/.18).

If we further assume that the LEC's potential productivity gain, X, is a linear function of the incentive for efficiency, I, then these same relationships should hold among X_{NS}, X_S, and X_{ROR}. And if that is so, the change from a price cap system with sharing to one without sharing should ultimately produce a much larger productivity increase -- about three times as much (94/29) -- as the change from the old ROR system to price caps with sharing.[2]

      b.   By itself, this analysis does not give us an estimate of $X_{NS} - X_S$. To generate such an estimate based on the SPR study, we must first find an estimate of $X_S - X_{ROR}$. Fortunately, there are a number of potential sources for such an estimate.

The most obvious is the Commission's original choice of a 0.5 percent CPD when it first adopted the price cap plan for the LECs. That number was chosen because the Commission believed the change from ROR to price cap regulation (even with sharing) would produce a productivity increase of at least that amount, and the Commission wanted to "assure that the *first* benefits of price caps flow to customers . . ." 5 FCC Rcd. at 6799. Because no one challenged that judgment on appeal, we can assume that this decision represented a reasonable judgment about the likely effects on productivity of moving from ROR to price caps with sharing (*i.e.*, $X_S - X_{ROR} = 0.5$). Accordingly, applying the SPR model, we would expect to see the LECs' potential X-factor increased by an additional 1.5 percent (approximately) based on the elimination of sharing. In other words, if $X_S - X_{ROR}$ is at least 0.5, as the Commission has long maintained, the SPR model predicts that $X_{NS} - X_S$ would be at least 1.5.

---

[2]Although the revision of the SPR model suggested by Ad Hoc (and alluded to in the *Further Notice*) does not permit a similar calculation of the effect of eliminating sharing, that revision appears consistent with this conclusion. Indeed, the Ad Hoc study is quite similar to the SPA study, except that it assumes that, even without price regulation, the gains from efficiency enhancements are more transitory (as a result of competition) than is assumed in the SPR study. As a result of this assumption, Ad Hoc calculates that a price cap plan with 50/50 sharing would produce 45 percent of the efficiency incentives that full competition would produce (so that I_S is .45 rather than .18 as in the SPA study), and that a pure price cap plan would produce about 86 percent of the efficiency incentives (*i.e.*, I_{NS} is .86 rather than .35 as in the SPA study). *See* Reply Comments of The Ad Hoc Telecommunications Users Committee, CC Docket No. 94-1 (June 29, 1994) at 16. Although the predicted incentives are higher in absolute terms, the relationship between them is approximately the same as in the SPR study, so the impact of moving from one system to the other should be about the same as well.

Other sources generate somewhat higher values for X_{NS} - X_S, but are generally consistent with these results. For example, in the Commission's TFP study (based on total company data), the average X-factor for 1986-1990 -- prior to price caps -- is approximately 5.5 percent, whereas the average X-factor for 1991-95 -- after price caps were implemented -- is approximately 6.1 percent. By itself, this analysis suggests that the move from ROR to price caps with a sharing mechanism increased the LECs' *potential* productivity by 0.6 percent (*i.e.*, X_S − X_{ROR} = .6). Under the SPR model, then, the move from price caps with sharing to price caps without sharing would be expected to increase potential productivity by an additional 1.8 percent (*i.e.*, X_{NS} - X_S = 1.8).

This analysis, however, can be refined in two respects to give a more accurate picture of the impact of the change in regulatory systems on X_{NS} - X_S. First, as shown in Table [B-14] of Appendix A, we can adjust the data in the staff's TFP study to reflect only interstate inputs and outputs. Second, we can hold constant all of the elements of the X-factor other than LEC productivity. Obviously, the change in the regulatory system for the LECs would not be expected to have an impact on input prices, either for the LECs or for other industries. Nor would it be expected to have an immediate impact on productivity in other industries, or on the economic forces that are affecting the productivity of *both* the LECs and the economy as a whole. Thus, to obtain a first-order approximation of the impact of the regulatory system on LEC productivity, we can simply look at trends in interstate LEC TFP growth.

As shown in Table A-9 of Appendix A, LEC TFP growth increased from 7.24 percent for the period 1986-1990, to 8.09 percent for the period 1991-95, a difference of 0.85 percent. Applying the SPR model thus suggests that X_{NS} - X_S would be 2.55 percent.[3] The Commission staff's results based on total company data, also shown on Table A-9, exhibit a similar pattern.

2.   Further corroborating evidence of the impact that the elimination of sharing had on the LECs' productivity is provided by the staff's imputed X Study (*Further Notice*, Appendix C). That study calculates the X-factors required in each year to maintain the LECs' average rate of return at the level of the previous year (as shown in Table C-4). These calculations show an average X factor of 7.66 for the years 1996 to 1998 – more than two percentage points higher than the 5.59 average computed for 1992 to 1995.[4]

---

[3] Indeed, the average differential TFP growth for 1996-1998, after the LECs were given the option of accepting a higher X in exchange for the elimination of sharing, was 8.93 percent – slightly more than one full percentage point above the 1991-95 level. This suggests that the Commission's limited efforts to move from price caps with sharing to price caps with sharing produced a further, *actual* increase in productivity of 1 percent. The latter figure, however, understates the *potential* increase from that change in regulatory regimes. Sharing was not eliminated for all LECs as of 1996 -- only those that thought they could profit substantially from the alternative regime. Thus, the complete elimination of sharing should produce an even larger efficiency gain. Moreover, the elimination of sharing was subject to legal challenge during that entire period, further dampening its impact on efficiency. And in all events, we have only three years of data since the LECs were given the option of avoiding sharing, as compared with five years' experience during the ROR period and the period in which sharing was mandatory.

[4] The 7.66 figure is a simple average of the X-factors calculated for 1996-1998: 7.90, 6.57, and 8.51. 5.95 is a simple average of the X-factors calculated for 1992-95: 5.50, 5.94, 5.51, and 6.83.

3.   Another alternative is to rely on the LECs' own apparent valuations of the efficiency impact of the sharing mechanism. Indeed, although it is not mentioned in the *Further Notice*, one of the most obvious indicators of the likely impact of the elimination of sharing is the actions taken by the price cap LECs in response to the option they were given in 1995 to increase their X-factor in return for the complete elimination of the sharing requirement.

The Commission's 1995 Price Cap Review Order gave the price cap LECs three alternatives for selecting the X-factor: a minimum X-factor of 4.0 percent with full sharing requirements, a 4.7 percent factor with a less restrictive sharing mechanism, and a 5.3 percent factor with no sharing requirement. These alternatives were available to the LECs for their tariff filings on July 1, 1995. Significantly, the vast majority of the price cap LECs chose the 5.3 percent X-factor with its no-sharing condition: eventually, five of the seven RBOCs elected the highest (5.3 percent) X-factor in return for the elimination of sharing.[5] And most of the non-RBOC price cap LECs also chose the 5.3 percent/no sharing alternative.[6] Thus, the bulk of the price cap LECS were willing to pay for the elimination of sharing by increasing their individual X-factor by 130 basis points.

This valuation by the price cap LECs themselves is strong evidence of the *minimum* increase in productivity that could be expected from the elimination of sharing. In other words, the LECs' own "revealed preferences" show that $X_{NS} - X_S$ is at least 1.3. And given that the actual value is probably much higher (as indicated by the LECs' persistent profitability), it would be reasonable for the FCC to adopt a CPD of approximately that amount.

To be sure, not all of the LECs have been willing to make this bargain. But, as the Commission has emphasized many times, the X-factor is designed, not to reflect the LECs' actual productivity experience, but the potential productivity gains that a LEC might reasonably expect. Even if some LECs did not believe they could increase their productivity by more than enough to make up for the 1.3 reduction in their X-factors, that does not prove that they could not do so. And it certainly does not prove that LECs in general could not do so. Indeed, the record shows that the vast majority of them were willing and able, in exchange for the elimination of sharing, to increase their productivity by *at least* 1.3 percentage points. This provides strong support for the conclusion that they could have increased their productivity slightly more – by 1.5 percentage points.

4.   The final step is to combine the CPD with the historical component of the X-factor. For the period through 2000, this is straightforward: a 1.5 percent CPD could simply be added to the 10.1 percent historical X-factor, which is based entirely on data through 1995,

---

[5]   The five RBOCs selecting the 5.3 percent X-factor were Ameritech, Bell Atlantic, BellSouth, PacTel, and Southwestern Bell. See Fourth Further Notice of Proposed Rulemaking, CC Dkt. No. 94-1, Sep. 27, 1995, FCC 95-406, ¶ 8 n.17.

[6]   The non-RBOC carriers selecting the 5.3 percent X-factor were United, Rochester, Lincoln, and GTE (38 out of 46 study areas). Id.

before the LECs had the option to eliminate sharing.

For the future, however, the analysis is arguably more complicated. While 1.5% represents the additional productivity growth that results from going from a sharing regime to a no-sharing regime, the historical X-factor (for 2000 forward) is based on periods characterized by both sharing and no-sharing options. Arguably, it may thus already reflect some of the additional productivity associated with the elimination of sharing.

However, the CPD can easily be adjusted to eliminate any risk of double-counting. If we assume, conservatively, that fully 1.5 percentage points of the X-factors for 1996, 1997, and 1998 are attributable to the (partial) elimination of sharing during that period, we get adjusted X-factors for those years of 8.8, 5.8, and 5.8, respectively. Using these values to calculate the rolling average X-factors as in Table A-5 yields an average X of 9.14 percent rather than 9.54 percent, suggesting that the X-factor during that period would have been 9.1 percent (after rounding) without the elimination of sharing. Because this is 0.4 percent less than the X-factor of 9.5 percent calculated in Table A-5 for future periods, we can eliminate any potential double-counting simply by reducing the CPD from 1.5 percent to 1.1 percent.

CERTIFICATE OF SERVICE

I hereby certify that on this 7th day of January, 2000, I caused true and correct

copies of the foregoing Comments of AT&T Corp. to be served on all parties by mailing, postage

prepaid to their addresses listed on the attached service list.

Dated: Washington, D.C.
         January 7, 2000
